## Homework 2

The results I received for the stock prediction are as follows:

```
'BAC')
'13.3518137067'
41.6068009278
                  'C')
140.739881951
                  'IBM')
                  'AAPL')
101.658941538
30.0482742801
                  'GE')
38.4262818254
                  'MCD')
120.122839572
58.8687730818
                  'NKE')
16.6564256764
                  'TWTR')
'207.960038529'
                  'TSLA')
```

In order to get the prediction for the 10 companies provided, I first gathered the prediction data. I did this using Yahoo! Finance. I retrieved the Yahoo! data between two specified dates – today's date and a previous date (in this case, February 1<sup>st</sup>, 2016). I also retrieved the data specified from Yahoo! Finance for today. The values I grabbed are the price when the stock market opens, the highest price for the day in the stock market, the lowest price, the current price, the volume of shares in a day, and the current price converted to a float. I additionally grabbed the closing price. These values are necessary for prediction. I predicted the price using the moving average of the last 14 days and the exponential moving average. The exponential moving average gives importance to the stocks closer to today. I also used the golden ratio, which is a Fibonacci ratio that is used in predictions to compare your previous price to your current price. Then, I outputted my results to the terminal. In order to improve my results, I could have potentially used a linear regression or Gaussian process.

```
